

Connection Logging

The following topics describe how to configure the Firepower System to log connections made by hosts on your monitored network:

- [Introduction to Connection Logging, page 1](#)
- [Connection Logging Strategies, page 2](#)
- [Logging Decryptable Connections with SSL Rules, page 8](#)
- [Logging Connections with Security Intelligence, page 8](#)
- [Logging Connections with Access Control Rules, page 9](#)
- [Logging Connections with a Policy Default Action, page 10](#)
- [Limiting Logging of Long URLs, page 11](#)

Introduction to Connection Logging

The system can generate logs of the connections its managed devices detect. These logs are called *connection events*. Settings in rules and policies give you granular control over which connections you log, when you log them, and where you store the data. Special connection events, called *Security Intelligence events*, represent connections blacklisted (blocked) by the reputation-based Security Intelligence feature.

Connection events contain data about the detected sessions. The information available for any individual connection event depends on several factors, but in general includes:

- Basic connection properties: timestamp, source and destination IP address, ingress and egress zones, the device that handled the connection, and so on
- Additional connection properties discovered or inferred by the system: applications, requested URLs, or users associated with the connection, and so on
- Metadata about why the connection was logged: which configuration handled the traffic, whether the connection was allowed or blocked, details about encrypted and decrypted connections, and so on

**Note**

You can supplement the connection logs gathered by your managed devices with connection data generated from exported NetFlow records. This is especially useful if you have NetFlow-enabled routers or other devices deployed on networks that your Firepower System managed devices cannot monitor.

Connection Logging Strategies

Log connections according to the security and compliance needs of your organization. If your goal is to limit the number of events you generate and improve performance, only enable logging for the connections critical to your analysis. However, if you want a broad view of your network traffic for profiling purposes, you can enable logging for additional connections.

**Tip**

To perform detailed analysis of connection data, Cisco recommends you log the ends of critical connections to the Firepower Management Center database.

Because the system can log a connection for multiple reasons, disabling logging in one place does not ensure that matching connections will not be logged. Also, unless you disable connection event storage, the system automatically logs some connections; for example, those associated with detected files, malware, and intrusions.

You cannot log connections fastpathed with 8000 Series fastpath rules.

Configurable Connection Logging

So that you log only critical connections, you enable connection logging on a per-rule basis within parent policies. If you enable connection logging for a rule, the system logs all connections handled by that rule. You can also log connections handled by policy default actions. Depending on the rule or default action (and for access control, a rule's inspection configuration), your logging options differ.

SSL Policy: Rules and Default Action

As part of access control, SSL policies handle encrypted traffic before evaluation by access control rules. You can log connections that match an SSL rule or SSL policy default action. For blocked connections, the system immediately ends the session and generates an event. For monitored connections and connections that you pass to access control rules, the system generates an event when the session ends.

Access Control Policy: Security Intelligence Decisions

You can log a connection whenever it is blacklisted (blocked) by the reputation-based Security Intelligence feature. Optionally, and recommended in passive deployments, you can use a monitor-only setting for Security Intelligence filtering. This allows the system to further analyze connections that would have been blacklisted, but still log the match to the blacklist. Security Intelligence monitoring also allows you to create traffic profiles using Security Intelligence information.

When the system logs a connection event as the result of Security Intelligence filtering, it also logs a matching Security Intelligence event, which is a special kind of connection event that you can view and analyze separately, and that is also stored and pruned separately. So that you can identify the blacklisted IP address in the connection, host icons next to blacklisted and monitored IP addresses look slightly different in the event viewer.

Access Control Policy: Rules and Default Action

You can log connections that match an access control rule or access control policy default action.

Automatic Connection Logging

Unless you disable connection event storage, the system automatically saves the following end-of-connection events to the Firepower Management Center database, regardless of any other logging configurations.

Connections Associated with Intrusions

The system automatically logs connections associated with intrusion events, unless the connection is handled by the access control policy's default action.

When an intrusion policy associated with the access control default action generates an intrusion event, the system does **not** automatically log the end of the associated connection. Instead, you must explicitly enable default action connection logging. This is useful for intrusion prevention-only deployments where you do not want to log any connection data.

An exception to this rule occurs if you enable beginning-of-connection logging for the default action. In that case, the system **does** log the end of the connection when an associated intrusion policy triggers, in addition to logging the beginning of the connection.

Connections Associated with File and Malware Events

The system automatically logs connections associated with file and malware events.

Note

File events generated by inspecting NetBIOS-ssn (SMB) traffic do not immediately generate connection events because the client and server establish a persistent connection. The system generates connection events after the client or server ends the session.

Beginning vs End-of-Connection Logging

You can log a connection at its beginning or its end, with the following exceptions for blocked traffic:

- **Blocked traffic**—Because blocked traffic is immediately denied without further inspection, usually you can log only beginning-of-connection events for blocked or blacklisted traffic. There is no unique end of connection to log.
- **Blocked encrypted traffic**—When you enable connection logging in an SSL policy, the system logs end-of-connection rather than beginning-of-connection events. This is because the system cannot determine if a connection is encrypted using the first packet in the session, and thus cannot immediately block encrypted sessions.

To optimize performance, log either the beginning or the end of any connection, but not both. Monitoring a connection for any reason forces end-of-connection logging. For a single non-blocked connection, the end-of-connection event contains all of the information in the beginning-of-connection event, as well as information gathered over the duration of the session.

The following table details the differences between beginning and end-of-connection events, including the advantages to logging each.

Table 1: Comparing Beginning and End-of-Connection Events

	Beginning-of-Connection Events	End-of-Connection Events
Can be generated...	When the system detects the beginning of a connection (or, after the first few packets if event generation depends on application or URL identification)	When the system: <ul style="list-style-type: none"> • Detects the close of a connection • Does not detect the end of a connection after a period of time • Can no longer track the session due to memory constraints
Can be logged for...	All connections except those blocked by the SSL policy	All connections, though you may not be able to configure end-of-connection logging in all places
Contain...	Only information that can be determined in the first packet (or the first few packets, if event generation depends on application or URL identification)	All information in the beginning-of-connection event, plus information determined by examining traffic over the duration of the session, for example, the total amount of data transmitted or the timestamp of the last packet in the connection
Are useful...	if you want to log: <ul style="list-style-type: none"> • Blocked connections • Only the beginning of a connection because the end-of-connection information does not matter to you 	If you want to: <ul style="list-style-type: none"> • Log encrypted connections handled by an SSL policy • Perform any kind of detailed analysis on, or trigger correlation rules using, information collected over the duration of the session • View connection summaries (aggregated connection data) in custom workflows, view connection data in graphical format, or create and use traffic profiles

Firepower Management Center vs External Logging

You can log connection and Security Intelligence events to the Firepower Management Center database (in the web interface, the **Event Viewer**). The number of events the Firepower Management Center can store depends on its model. You can also log events to an external syslog or SNMP trap server, using a connection you configure called an *alert response*.

Logging to the Firepower Management Center database allows you to take advantage of many reporting, analysis, and data correlation features of the Firepower System. For example:

- Dashboards and the Context Explorer provide you with graphical, at-a-glance views of the connections logged by the system.

- Event views present detailed information on the connections logged by the system, which you can display in a graphical or tabular format or summarize in a report.
- Traffic profiling uses connection data to create a profile of your normal network traffic that you can then use as a baseline against which to detect and track anomalous behavior.
- Correlation policies allow you to generate events and trigger responses (such as alerts or external remediations) to specific types of connections or traffic profile changes.

**Note**

To use these features, you **must** log connections (and in most cases, the end of those connections rather than the beginning) to the Firepower Management Center database. This is why the system automatically logs critical connections—those associated with logged intrusions, prohibited files, and malware.

Actions and Connection Logging

Where you can configure connection logging, rule actions and policy default actions determine not only how the system inspects and handles matching traffic, but also when and how you can log details about matching traffic. Connection events contain metadata about why the connection was logged, including which configurations handled the traffic.

Logging for Monitored Connections

The system always logs the ends of connections for traffic matching the following configurations, even if the traffic matches no other rules and you do not enable default action logging:

- Security Intelligence—Blacklists set to monitor (also generates a Security Intelligence event)
- SSL rules—**Monitor** action
- Access control rules—**Monitor** action

The system does not generate a separate event each time a single connection matches a Monitor rule. Because a single connection can match multiple Monitor rules, each connection event can include and display information on the first eight Monitor access control rules that the connection matches, as well as the first matching SSL Monitor rule.

Similarly, if you send connection events to an external syslog or SNMP trap server, the system does not send a separate alert each time a single connection matches a Monitor rule. Rather, the alert that the system sends at the end of the connection contains information on the Monitor rules the connection matched.

Logging for Trusted Connections

You can log the beginnings and ends of trusted connections, which includes traffic matching the following rules and actions:

- Access control rules—**Trust** action
- Access control default action—**Trust All Traffic**

Trusted connections are not subject to deep inspection or discovery, so connection events for trusted connections contain limited information.

The system logs TCP connections handled by a Trust access control rule differently depending on the device that detected the connection:

- For 7000 and 8000 Series devices, TCP connections detected by a Trust rule on the first packet generate different events depending on the presence of a preceding enabled Monitor rule. If the Monitor rule is active, the system evaluates the packet and generates both a beginning and end-of-connection event. If no Monitor rule is active, the system only generates an end-of-connection event.
- For all other models, TCP connections detected by a Trust rule on the first packet only generate an end-of-connection event. The system generates the event one hour after the final session packet.

Logging for Blocked Connections

You can log blocked connections, which includes traffic matching the following rules and actions:

- Security Intelligence—Blacklists set to block (also generates a Security Intelligence event)
- SSL rules—**Block** and **Block with reset** actions
- SSL default action—**Block** and **Block with reset**
- Access control rules—**Block**, **Block with reset**, and **Interactive Block** actions
- Access control default action—**Block All Traffic**

Only devices deployed inline (that is, using routed, switched, or transparent interfaces, or inline interface pairs) can block traffic. Because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

Caution

Logging blocked TCP connections during a Denial of Service (DoS) attack can affect system performance and overwhelm the database with multiple similar events. Before you enable logging for an Block rule, consider whether the rule monitors traffic on an Internet-facing interface or other interface vulnerable to DoS attack.

Beginning vs End-of-Connection Logging for Blocked Connections

When you log a blocked connection, how the system logs it depends on why the connection was blocked; this is important to keep in mind when configuring correlation rules based on connection logs:

- For SSL rules and SSL policy default actions that block encrypted traffic, the system logs **end-of-connection** events. This is because the system cannot determine if a connection is encrypted using the first packet in the session.
- For other blocking actions, the system logs **beginning-of-connection** events. Matching traffic is denied without further inspection.

Logging Bypassed Interactive Blocks

Interactive blocking access control rules, which cause the system to display a warning page when a user browses to a prohibited website, allow you to configure end-of-connection logging. This is because if the user clicks through the warning page, the connection is considered a new, allowed connection which the system can monitor and log.

Therefore, for packets that match an Interactive Block or Interactive Block with reset rule, the system can generate the following connection events:

- a beginning-of-connection event when a user's request is initially blocked and the warning page is displayed; this event has an associated action of `Interactive Block` or `Interactive Block with reset`
- multiple beginning- or end-of-connection events if the user clicks through the warning page and loads the originally requested page; these events have an associated action of `Allow` and a reason of `User Bypass`

Logging for Allowed Connections

You can log allowed connections, which includes traffic matching the following rules and actions:

- SSL rules—**Decrypt** action
- SSL rules—**Do not decrypt** action
- SSL default action—**Do not decrypt**
- Access control rules—**Allow** action
- Access control default action—**Network Discovery Only** and any intrusion prevention option

Enabling logging for these configurations ensures the connection is logged, while also permitting (or specifying) the next phase of inspection and traffic handling. SSL logging is always end-of-connection; access control configurations also allow beginning-of-connection logging.

When you allow traffic with an access control rule or default action, you can use an associated intrusion policy to further inspect traffic and block intrusions. For access control rules, you can also use a file policy to detect and block prohibited files, including malware. Unless you disable connection event storage, the system automatically logs most allowed connections associated with intrusion, file, and malware events. For detailed information, see [Automatic Connection Logging, on page 3](#). Note that connections with encrypted payloads are not subject to deep inspection, so connection events for encrypted connections contain limited information.

File and Malware Event Logging for Allowed Connections

When a file policy detects or blocks a file, it logs one of the following events to the Firepower Management Center database:

- *file events*, which represent detected or blocked files, including malware files
- *malware events*, which represent detected or blocked malware files only
- *retrospective malware events*, which are generated when the malware disposition for a previously detected file changes

You can disable this logging on a per-access-control-rule basis. Or, disable file and malware event storage entirely.

**Note**

Cisco recommends you leave file and malware event logging enabled.

Logging Decryptable Connections with SSL Rules

Smart License	Classic License	Supported Devices	Supported Domains	Access
Threat	Protection	Any	Any	Admin Access Admin Network Admin

So that you log only critical connections, you can enable connection logging on a per-rule basis. If you enable connection logging for a rule, the system logs all connections handled by that rule.

Procedure

-
- Step 1** In the SSL policy editor, click the edit icon (✎) next to the rule where you want to configure logging. If a view icon (🔍) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 2** Click the **Logging** tab.
- Step 3** Check **Log at End of Connection**.
For monitored traffic, end-of-connection logging is required.
- Step 4** Specify where to send connection events.
Send events to the event viewer if you want to perform Firepower Management Center-based analysis on these connection events. For monitored traffic, this is required.
- Step 5** Click **Save** to save the rule.
- Step 6** Click **Save** to save the policy.
-

Logging Connections with Security Intelligence

Smart License	Classic License	Supported Devices	Supported Domains	Access
Threat	Protection	Any	Any	Admin Access Admin Network Admin

Procedure

Step 1 In the access control policy editor, click the **Security Intelligence** tab.

Step 2 Click the logging icons () to enable Security Intelligence logging using the following criteria:

- By IP address—Click the logging icon next to **Networks**.
- By URL—Click the logging icon next to **URLs**.
- By Domain Name—Click the logging icon next to the **DNS Policy** drop-down list.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Check the **Log Connections** check box.

Step 4 Specify where to send connection and Security Intelligence events.

Send events to the event viewer if you want to perform Firepower Management Center-based analysis, or if you want to set blacklisted objects to monitor-only.

Step 5 Click **OK** to set logging options.

Step 6 Click **Save** to save the policy.

What to Do Next

- Deploy configuration changes; see [Deploying Configuration Changes](#).

Logging Connections with Access Control Rules

Smart License	Classic License	Supported Devices	Supported Domains	Access
Any	Any	Any	Any	Admin/Access Admin/Network Admin

Within an access control policy, access control rules provide a granular method of handling network traffic across multiple managed devices. So that you can log only critical connections, you enable connection logging on a per-access-control-rule basis—if you enable connection logging for a rule, the system logs all connections handled by that rule. Depending on the rule action and intrusion and file inspection configuration of the rule, your logging options differ.

Note that even if you disable logging for an access control rule, end-of-connection events for connections matching that rule may still be logged to the Firepower Management Center database if the connection contains an intrusion attempt, prohibited file, or malware; was inspected and logged by an SSL policy; or previously matched at least one access control Monitor rule.

Procedure

-
- Step 1** In the access control policy editor, click the edit icon (✎) next to the rule where you want to configure logging. If a view icon (🔍) appears instead, the configuration is inherited from an ancestor policy, belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 2** Click the **Logging** tab.
- Step 3** Specify whether you want to **Log at Beginning of Connection** or **Log at End of Connection**. To optimize performance, log either the beginning or the end of any connection, but not both.
- Step 4** Check the **Log Files** check box to specify whether the system should log any file and malware events associated with the connection. Cisco recommends you leave this option enabled if the rule invokes file or malware inspection.
- Step 5** Specify where to send connection events. You **must** send events to the Firepower Management Center if you want to perform Management Center-based analysis on these connection events, or if the rule action is **Monitor**.
- Step 6** Click **Save** to save the rule.
-

Logging Connections with a Policy Default Action

Smart License	Classic License	Supported Devices	Supported Domains	Access
Any	Any	feature dependent	Any	Admin Access Admin Network Admin

A policy's default action determines how the system handles traffic that matches none of the rules in the policy (except Monitor rules, which match and log—but do not handle or inspect—traffic). Logging settings for the SSL policy default action also govern how the system logs undecryptable sessions.

Procedure

-
- Step 1** In the policy editor, click the logging icon (📄) next to the **Default Action** drop-down list.
- Step 2** Specify whether you want to **Log at Beginning of Connection** (not supported for SSL) or **Log at End of Connection**. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration. In an access control policy, the configuration may also be inherited from an ancestor policy.

When you have the option, to optimize performance, log either the beginning or the end of any connection, but not both. For the access control **Block All Traffic** default action, because blocked traffic is immediately denied without further inspection, you cannot log the end of the connection.

- Step 3** Specify where to send connection events.
Send events to the event viewer if you want to perform Firepower Management Center-based analysis on these connection events.
- Step 4** Click **OK**.
- Step 5** Click **Save** to save the policy.

What to Do Next

- Deploy configuration changes; see [Deploying Configuration Changes](#).

Limiting Logging of Long URLs

Smart License	Classic License	Supported Devices	Supported Domains	Access
Any	Any	Any	Any	Admin Access Admin Network Admin

End-of-connection events for HTTP traffic record the URL requested by monitored hosts. Disabling or limiting the number of stored URL characters may improve system performance. Disabling URL logging (storing zero characters) does not affect URL filtering. The system filters traffic based on requested URLs even though the system does not record them.

Procedure

- Step 1** In the access control policy editor, click the **Advanced** tab, then click the edit icon (✎) next to **General Settings**.
If a view icon (🔍) appears instead, the configuration is inherited from an ancestor policy, belongs to an ancestor domain, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 2** Enter the **Maximum URL characters to store in connection events**.
- Step 3** Click **OK**.
- Step 4** Click **Save** to save the policy.

What to Do Next

- Deploy configuration changes; see [Deploying Configuration Changes](#).
